Abstract

Background: Most of trematodes need snails to complete their life cycles. Consequently freshwater snails are served as intermediate hosts of many parasites worldwide. There is a lack of report on snail diversity and parasitic infection in snails in Sirindhorn Reservoir, Ubon Ratchathani province, Thailand.

Methods: Mollusk diversity and trematode cercariae infections were investigated in snails from 120 sampling sites around Sirindhorn Reservoir from April 2018 to June 2018. Mollusk species were identified based on their shell morphology. The presence of cercariae infections in snails was examined by cercarial shedding methods. The interaction between snail species was analyzed by the correlation method.

Results: Overall, 2076 mollusks were collected which comprised six species of snails and two species of bivalves. Snail species were identified as Bithynia siamensis goniocephala, Anentome benula, Filopaludina sumatrensis spicosa, F. martensi martensi, F. martensi munensis and Pomacea canaliculata. The overall rate of trematode cercariae infection was 1.69% (35/2,076). The cercariae found infecting snails were Cercariaeum cercaria, Virgulate cercaria, Cotylomicrocercous cercaria and Furcocercous cercaria. The most common snails found was the assassin snail, A. benula, which showed the negative relationship among other species interactions.

Conclusion: This finding indicated infection with animal’s parasites in snails in this area are common, besides, we found many species of snails in Sirindhorn Reservoir are potentially be the host of parasite in animal and human.

Introduction

Infection with trematode parasite remains medically importance problem worldwide especially in neglected countries (1,2). To complete the trematode parasites life cycle, snails are required to be the intermediate host. In snail host, the trematode eggs can hatch in the environment to be miracidia which can penetrate into snail intermediate hosts (3) or eggs can hatch within the gastrointestinal tract of the snails (4). After the miracidia infection, they can develop and transform to be sporocyst, redia and cercaria stages. The cercaria will be released from infected snails for finding the new host or transformation to be metacercaria stage in further. Currently, quickly increased snails number are emerging problems worldwide, especially in the area where a dam is situated since they can spread extensively snail borne parasitic diseases (5-7). Although infection rate of snails is very low, they can release a numerous number of the parasite larva (8). Accordingly, the study of epidemiology of snails and their infected cercariae is extra essential and need to be concern.

In Thailand, the studies related to snails diversity and cercarial infection are insufficient (9-11), especially in Sirindhorn Reservoir where is an important area used for agricultural purposes, animal husbandry, also the source of fish farming. No study has been surveyed snail diversity and parasitic infection in snail in Sirindhorn Reservoir, Ubon Ratchathani province of Thailand (Fig. 1). Mollusks were collected by hand for a period of 5 min/station per trained person (12,13) from the coast of the reservoir where the waterbed is sandy, soil, mud and rocks. Mollusks were kept in plastic bags with holes during transport to the laboratory for further study. Mollusks were identified based on shell and operculum morphology (14,15).

All experimental procedures using animals were approved by the Animal Care and Use Committee, Ubon Ratchathani Rajabhat University (AE612008).

Examination of cercarial infection in snails

To examine trematode infection in snails, cercarial shedding method was performed according to the previous study (16). Briefly, snails were cleaned to remove mud and plant materials with dechlorinated tap water. Each snail was measured, placed in a small cup (3 cm in diameter and 2.5 cm in high) containing 10 ml of dechlorinated tap water. For daytime, shedding was performed by turn on an electric light for 3 hours to induce releasing of cercariae from the infected snails. For nighttime, cups of snails were kept in the darkness overnight. Cercarial shedding was performed both daytime and nighttime and observed cercariae under the stereomicroscope (13-17). The presence of cercariae was identified based on their morphology and movement under the stereomicroscope by identification key (18). Non-infected snails were delivered back to the Sirindhorn Reservoir.

Materials and Methods

Study area and sample collection

The freshwater mollusks were collected during Apr 2018 to Jun 2018 which is overlap between summer season and rainy season, temperature ranging from 24-36 °C and the annually rainfall is 1600-1800 mm (Thai Meteorological Department, 2017). Samples were collected from 12 localities (1 locality consists of 10 stations where were 10-15 meters far from each other) surround Sirindhorn Reservoir, Ubon Ratchathani province of Thailand (Fig. 1). Mollusks were collected by hand for a period of 5 min/station per trained person (12,13) from the coast of the reservoir where the waterbed is sandy, soil, mud and rocks. Mollusks were kept in plastic bags with holes during transport to the laboratory for further study. Mollusks were identified based on shell and operculum morphology (14,15).

Data analysis

Snail size was expressed as the mean ± standard error. The infection rate was ex-
pressed as percentage. The interaction between snail species was analyzed. Correlation of species interaction was performed using the R project for Statistical Computing (https://www.r-project.org/). Statistically significant was defined as $P$ less than 0.05.

**Results**

**Situation of mollusk in Sirindhorn reservoir**

The present study represents the first report on species diversity and cercariae trematode infection in snails in Sirindhorn Reservoir. A total of 2,076 mollusks collected were classified into 4 families, 4 genus and 6 species of gastropod snails: the Nassariidae (Anentome helena), Bithyniidae (Bithynia siamensis goniomphalos), Viviparidae (Filopaludina sumatrensis spiciosa, F. martensi martensi, F. martensi munensis) and Ampullariidae (Pomacea canaliculata) in addition 2 families, 2 genus and 2 species of bivalves: Cyrenidae (Corbicula sp.) and Unionidae (Pilsbryoconcha exilis) (Fig. 2).

In total, 2,000 specimens belonging to snails, 53.66% (1,114/2,076) were the assassin snail, $A. helena$, 16.57% (344/2,076) were $F. s. spiciosa$, 12.67% (263/2,076) were $B. s. goniomphalos$, 10.55% (219/2,076) were $F. m. munensis$, 2.36% (49/2,076) were $F. m. martensi$ and 0.53% (11/2,076) were $P. canaliculata$. Additionally, among 76 specimens of bivalves, 3.37% (70/2,076) were $C. orbicula$ sp. and 0.29% (6/2,076) were $P. exilis$ (Table 1).

**Fig. 1:** Map of 12 localities in Sirindhorn Reservoir, Ubon Ratchathani province, Thailand where mollusk samples were collected.

**Fig. 2:** Shell morphology of six snails and two bivalves in Sirindhorn Reservoir. $A = Pomacea canaliculata$; $B = Corbicula sp.$; $C = Pilsbryoconcha exilis$; $D = Bithynia siamensis goniomphalos$; $E = Anentome helena$; $F = Filopaludina sumatrensis spiciosa$; $G = Filopaludina martensi munensis$; $H = Filopaludina martensi martensi$. Scale bar: $A$-$H = 1$ cm.

Trematode cercariae infection

Three species of snails namely, B. s. goniomphalos, A. helena and F. s. spiciosa were found as the intermediate host of cercariae which were Cotylomicrocercous cercaria, Virgulate cercaria, Cercariaeum cercaria and Furcocercous cercaria (Fig. 3). The infection rate of Virgulate cercaria was 4.18% in B. s. goniomphalos, 0.09% in A. helena and 0.29% in F. s. spiciosa. The infection rate of Cercariaeum cercaria were 0.38% in B. s. goniomphalos. Snail A. helena were infected with 1.80% of Cotylomicrocercous cercariae and 0.09% of Furcocercous cercariae (Table 2).

Relationship between species interactions and Assassin snail abundance

The relationship between species interactions and A. helena (assassin snail) richness were analyzed. The relative abundance of A. helena was statistically negative correlation with the presence of F. martensi \((r = -0.303; P<0.05)\) and Filopaludina spp. \((r = -0.258; P<0.05)\). Moreover, the species richness was found negative correlation trend between A. helena and B. s. goniomphalos \((r = -0.341; P=0.07)\) but no statistically relationship (Fig. 4).

Fig. 4: Relationship between assassin snail, A. helena, abundance and species interactions: A: Negative correlation with F. martensi \((r = -0.303; P<0.05)\); B: Negative correlation with Filopaludina spp. \((r = -0.258; P<0.05)\); C: Negative correlation on density with B. s. goniomphalos \((r = -0.341; P=0.07)\)

Discussion

Several research have reported mollusk diversity and their potential roles to be the intermediate host of the parasites (19-20). In this study, we found six species of snails, some of them have been reported as the host of parasite namely, B. s. goniomphalos, Filopaludina sp. and P. canicalata. Snail B. s. goniomphalos is the first intermediate host of a human liver fluke, Opisthorchis viverrini, the infected snail can

Available at: http://ijpa.tums.ac.ir
release cercariae to infect cyprinoid fish in the next step (21-22). Snail Filopaludina sp. is the host of Echinostomes intestinal fluke, the infected snails able to be the second intermediate host of metacercariae (23). Snail P. canaliculata is the intermediate host of the rat lungworm, Angiostrongylus cantonensis (24-25). Our finding indicated that some of snail species in this area can potentially be host of medical parasites.

From cercarial examination, four type cercariae were found which are Cotylomicrocercous cercaria (parasite of fish), Virgulate cercaria (intestinal parasites of birds and amphibians), Cercariaeum cercaria (intestinal parasites of fish and parasites of the respiratory tract of birds) (18) and Furcocercous cercaria (blood parasite of vertebrate animals). The total infection rate of cercariae in Sirindhorn reservoir was 1.69% (35/2,076) which lower than the reported of cercarial infections in snails in Chao-Phraya Basin (5.90%) (9) Chiang Mai province, Thailand (17.27%) (10) and Nakhon Nayok Province, Thailand (4.7%) (11), these may due to the difference of water reservoirs and snails diversity in each water area.

In Sirindhorn reservoir, snail F. s. spiciosa were infected with Virgulate cercariae (0.29%) but not found infection of this snail in Nakhon Nayok Province, Thailand (11). B. s. goniomphalos in Sirindhorn reservoir is infected with Virgulate cercaria (4.18%) which supported the previous report regarding the presence of Virgulate cercaria in this snail (13-17). Moreover, this snail is infected with Cercariaeum cercaria (0.38%) which has not been reported in any study in Thailand. Besides, our study found no bithyniid snail infected with human liver fluke, Opisthorchis viverrini, supporting to the study of metacercaria in fish in this area which found only 4 metacercaria of O. viverrini (observed from 840 cyprinoid fish) (26) indicated that infection rate in the intermediate host is relatively low due to Ubon Ratchathani is an endemic area of opisthorchiasis where the infection rate in human is 14.8% (27).

In addition, we found A. helena served as the intermediate host of Cotylomicrocercous cercariae, Furcocercous cercariae and Virgulate cercariae which different across Chao-Phraya Basin (9) Nakhon Nayok Province, Thailand (11) where A. helena snail did not reveal any infections. However, our finding supported the study of trematode infection in Clea which found Clea collected from four provinces (Nakhon Ratchasima, Buri Ram, Surin and Si Sa Ket) of Thailand are infected with 1.92% of at least one types of Furcocercous cercariae, Cotylomicrocercous cercariae and Cercariaeum cercariae (28).

In many countries, freshwater snails have been surveyed and examined for parasitic infections such as Iran (29), Sri Lanka (30), Sudan (31) and Zimbabwe (32). A total of 27.9%, 16%, 14.1% and 6.6% of collected snails from Iran, Sri Lanka, Sudan and Zimbabwe, respectively, released one or more types of cercariae. The difference of cercarial types and infection rates of snails in each area may as a result of the difference of water habitat, endemic area of parasites, species diversity of snail, including the Anthropocene alteration of water environments.

In this study, A. helena was the dominant species of snails found in every localities sampling. The highest number of A. helena snails were found in areas with sandy groundfollowed soil, mud and rock which according to the presence of B. s. goniomphalos. In contrast, F. martensi and F. s. spiciosa were preferred muddy area. When analyzed the relationship between species interaction, we found negative correlation between assassin snails (A. helena) and Filopaludina spp. (P < 0.05) also B. s. goniomphalos (P = 0.07). This finding may be occurred from character of predator of assassin snails, preference habitat and food. A. helena has recently been reported as the biological predator which consumed Melanoideos tuberculata and Tarebia granifera snails in a large amount (33), but in the presence of organic residues, the intensity of consumption of M. tuberculata and T. granifera snails by assassin snails is sig-

Available at: [http://ijpa.tums.ac.ir](http://ijpa.tums.ac.ir)
nificantly reduced (34). Due to the ability of mollusks predatory, A. helena targeted by the freshwater ornamental pet trade as a result of its predation abilities on other snail species (35). Moreover, as we were sampling mollusks, we found A. helena were consuming Corbicula sp., B. s. goniomphalos and Filopaludina spp. (Fig. 5), this event supported the data of future snail-control strategies by using assassin snails.

![Fig. 5: A. helena were consuming Corbicula sp. (A), B. s. goniomphalos (B) and F. s. speciosa (C)](image)

**Conclusion**

Species diversity of snails surround Sirindhorn Reservoir, Ubon Ratchathani province were observed. This study provides data of snail diversity which some of them have been reported as intermediate host of medical parasites and types of infected cercariae in snails which are important for the veterinary and public health.

Furthermore, we also observed the relationship between densities of assassin snails, A. helena, and other competitive snails and found negative correlation trends which need for extra study whether A. helena can act as the predator of medical mollusk. And whether using A. helena to consume other snails can get positive results in controlling snail-borne parasitic diseases or not.
